# 1 Finite Automata

#### 1.1 Deterministic finate automaton - DFA

is a 5-tuple  $(Q, \Sigma, \delta, q_0, F)$  where:

- Q is a finate set of states,
- $\Sigma$  is a finite input alphabet
- $q_0 \in Q$  is the *initial state*,
- $F \subseteq Q$  is the set of *final states*, and
- $\delta$  is the transition function, i.e.  $\delta: Q \times \Sigma \to Q$ For each state, there must be a transition for every input symbol out of  $\Sigma$ .

**exp.** Dfa for finding modulo of binary numbers

Suppose our modulo is m. Then for every possible remainder, there must be a state in fa  $\{q_0, q_1, \ldots, q_{m-1}\}.$ 

- state  $q_0: m*k+0$   $m*k | 0 \Rightarrow 2*(5k) + 0 = m*k+0 \text{ (on } 0, \text{ we go to } q_0)$  $m*k | 1 \Rightarrow 2*(5k) + 1 = m*k+1 \text{ (on } 1, \text{ we go to } q_1)$
- state  $q_1: k+1$   $m*k | 0 \Rightarrow 2*1+0=2 \text{ (go to } q_2)$  $m*k | 1 \Rightarrow 2*1+1=3 \text{ (go to } q_3)$
- state  $q_{m-1}: k + (m-1)$   $m * k | 0 \Rightarrow 2 * (m-1) + 0$  $m * k | 1 \Rightarrow 2 * (m-1) + 1$

If your remainder is bigger than m, then you must modulo it!

#### 1.2 Nondeterministic finate automaton - NFA

is a 5-tuple  $(Q, \Sigma, \delta, q_0, F)$  where:

- $Q, \Sigma, q_0, F$  read dfa
- $\delta$  is the transition function, i.e.  $\delta: Q \times \Sigma \to 2^Q$ That is  $\delta(q, a)$  is the set of all states p such that there is a transition labeled from a to p.

**1.3 NFA** with epsilon moves -  $NFA_{\epsilon}$ 

is a 5-tuple  $(Q, \Sigma, \delta, q_0, F)$  where:

- $Q, \Sigma, q_0, F \text{ read } dfa$
- $\delta$  is the transition function, i.e.  $\delta: Q \times (\Sigma \cup \{\epsilon\}) \to 2^Q$ That is  $\delta(q, a)$  is the set of all states p such that there is a transition labeled from a to p, where a is either a symbol in  $\Sigma$  or  $\epsilon$ .

 $\epsilon$ -closure defines which  $\epsilon$  transitions are allowed from a single state in a fa (set of states we can reach).

**exp.** NFA for  $L^c$ 

$$NFA(L) \to DFA(L) \to DFA(L^c)$$

Due to the properties of **DFA**, the complementation is applied just by switching final and non-final states of fa.

# 2 Regular expressions

### 2.1 Regular operations

Let  $L_1, L_2$  be some regular languages. Then their

- union  $\rightarrow L_1 \cup L_2 = \{ \forall x : x \in L_1 \text{ or } x \in L_2 \}$
- concatenation  $\rightarrow L_1.L_2 = L_1L_2$
- kleene closure  $\rightarrow = L^*$
- interscetion  $\rightarrow L_1 \cap L_2$
- ullet complementation  $ightarrow \overline{L}$

are also regular languages. Regexp are equialent with NFA.

**2.2 Pumping lemma for regular languages** Let R be a class of regular languages. Then language  $L \in R \to \exists n > 0$ :

$$\forall z \in L, |z| \geq n: \\ \exists u, v, w: \ |uv| \leq n, |v| \geq 1, z = uvw \rightarrow \forall i \geq 0: uv^i w \in L$$

if we negate lemma, we can prove that some languages are irregular

$$\forall n>0: \exists z\in L, |z|\geq n \\ \forall u,v,w: \ |uv|\leq n, |v|\geq 1, z=uvw \rightarrow \exists i\geq 0: uv^iw\notin L \Rightarrow L\notin R$$

# 3 Context-free grammars

- **3.1 Definition:** A context-free grammar (CFG) is a 4-tuple G = (V, T, P, S) where:
  - ullet V is a finite set of variables
  - $\bullet$  T is a finite set of terminals
  - P is a finite set of productions each of which is of the form  $A \to \alpha$ , where  $A \in V$  and  $\alpha$  is a word in the language  $(V \cup T)^*$
  - S is a special variable called the start symbol

**Ambiguity**: A CFG is said to be ambiguous if some word has more than one derivation tree.

**exp.** regex to CFG conversion

Suppose we have a regex:  $a(ab)^*bb(aa+b)^*a$ 

Then we could model a CFG for it as:

- $S \rightarrow XYZUV$
- $\bullet X \to a$
- $Y \to abY | \epsilon$
- $Z \rightarrow bb$
- $U \rightarrow aaU|bU|\epsilon$
- $\bullet V \rightarrow a$
- 3.2 Pumping lemma for context-free languages Let L be a CFL.

$$\begin{split} \exists n > 0: \\ \forall z \in L, |z| \geq n: \\ \exists u, v, w, x, y: \ |vwx| \leq n, |vx| \geq 1 \\ z = uvwxy \rightarrow \forall i \geq 0: uv^i wx^i y \in L \end{split}$$

if we negate lemma, we can prove that some languages are not context-free.

$$\begin{aligned} \forall n > 0: \\ \exists z \in L, |z| \geq n: \\ \forall u, v, w, x, y: \ |vwx| \leq n, |vx| \geq 1 \\ z = uvwxy \rightarrow \exists i \geq 0: uv^i wx^i y \notin L \end{aligned}$$

# 4 Pushdown Automata

- **4.1 Definition:** A pushdown automaton (PDA) is a 7 tuple  $M = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$  where:
  - $Q, \Sigma, q_0, F$  read dfa
  - $\Gamma$  is the stack alphabet
  - $Z_0 \in \Gamma$  is the start stack symbol, and
  - δ is the transition function
     i.e. a mapping from Q × (Σ ∪ {ε}) × Γ to finite subsets of Q × Γ\*
     → 2<sup>Q</sup>×Γ\*
- **4.2** Accepted languages of the PDA

For PDA  $M = (Q, \Sigma, \Gamma, \delta, q_0, Z_0, F)$  we define two languages:

- L(M), the language accepted by final state, to be  $L(M) = \{w \in \Sigma^* | (q_0, w, Z_0) \to^* (p, \epsilon, \gamma) \}$  for some  $p \in F$  and  $\gamma \in \Gamma^* \}$
- L(M), the language accepted by empty stack, to be  $N(M) = \{w \in \Sigma^* | (q_0, w, Z_0) \to^* (p, \epsilon, \epsilon); \text{ for some } p \in Q\}$

#### **4.3** The class of CFLs is **closed** under:

union, concatenation, kleene closure, substitution, inverse homomorphism

The class of CFLs is *not* **closed** under: intersection, complementation.

But is closed for intersection if both CFL represent some regular sets.

# 5 Touring Machines

# **5.1 Definition:** A basic Toruing Machine (TM) is a 7-tuple $M = \{Q, \Sigma, \Gamma, \delta, q_0, B, F\}$ where:

- ullet Q is a finite set of states
- $\Sigma$  is the input alphabet
- $\Gamma$  is the tape alphabet  $B \in \Gamma => \Sigma \subseteq \Gamma$
- $\bullet$   $\delta$  is the transition function
- $q_0$  is the *initial state* and,
- $F \subseteq Q$ : is the set of final states

#### 5.2 TM modifications:

- Finite storage  $\Rightarrow \delta: Q \times \Gamma \times \Gamma^k \to Q \times \Gamma \times \{L, R, S\} \times \Gamma^k$
- Multiple track tape  $\Rightarrow \delta: Q \times \Gamma^{tk} \to Q \times \Gamma^{tk} \times \{L, R, S\}$
- Two-way infinite tape  $\Rightarrow \delta: Q \times \Gamma \to Q \times \Gamma \times \{L, R, S\}$
- Multiple tapes  $\Rightarrow \delta: Q \times \Gamma^{tp} \to Q \times (\Gamma \times \{L, R, S\})^{tp}$
- Multidimensional tape  $\Rightarrow$   $\delta$  :  $Q \times \Gamma \rightarrow Q \times \Gamma \times \{L_1, R_1, \dots, L_d, R_d, S\}$

## 5.3 Universal Touring Machine (UTM)

is a TM, that accepts some *Touring machine* M description and a word w. The universal TM then decides if  $w \in L(M)$ .

[TM description|w]  $111 < q_1 > 11 < q_2 > 11 \dots 11 < q_k > 111w$ 

- $\rightarrow$  language L is **semi-decidable**, if there exists a TM, which: for every  $w \in L$ , TM halts in a final state
  - $\rightarrow$  language L is **decidable**, if there exists a TM, which:

for every  $w \in L$ , TM halts in a final state

for every  $w \notin L$ , TM halts in a non-final state

 $\rightarrow$  language L is **undecidable**, if it is not decidable.

#### 5.4 Theorems for sets

Let S, A, B be arbitrary sets. Then:

- S is  $decidable \Rightarrow S$  is semi-decidable
- S is  $decidable \Rightarrow \overline{S}$  is decidable
- S and  $\overline{S}$  are semi-decidable  $\Rightarrow$  S is decidable
- A and B are semi-decidable  $\Rightarrow A \cap B \& A \cup B$  are semi-decidable
- A and B are  $decidable \Rightarrow A \cap B \& A \cup B$  are decidable

## 5.5 Three possibilities for set complementation:

- S and  $\overline{S}$  are decidable
- S and  $\overline{S}$  are *undecidable*, one is semi, and the other is not.
- S and  $\overline{S}$  are *undecidable*, and neither is semi-decidable.

#### 5.6 Known languages:

- Diagonalizable language  $\to L_d = \{ < M > | < M > \notin L(M) \}$  undecidable / not semi-decidable.
- Universal language  $\to L_u = \{(< M >, w) | w \in L(M)\}$  semi-decidable, but not decidable.

- Empty language  $\rightarrow L_e\{\langle M \rangle | L(M) = \{\}\}$  undecidable
- Non-Empty language  $\to L_{ne} = \{ < M > | L(M) \neq \{ \} \}$  semi-decidable, but not decidable.

#### 5.6 Rice's theorem for (not)semi-decidabilty:

- 1.  $L \in S \land L \subseteq L' \Rightarrow L' \in S$
- 2.  $L \in S \land L \ infinite \Rightarrow \exists L' \subseteq L : L \in S, \ L' \ finite$
- 3. in numerability of final sets in  ${\cal S}$ 
  - $(1) \wedge (2) \wedge (3) \Leftrightarrow L_s$  is semi-decidable

# 6 Complexity classes

## 6.1 In terms of formal languages:

- DTIME $(T(n)) = \{L | L \text{ is a language } \land L \text{ has time complexity } T(n)\}$
- DSPACE $(S(n)) = \{L | L \text{ is a language } \land L \text{ has space complexity } S(n)\}$
- NTIME $(T(n)) = \{L | L \text{ is a language } \land L \text{ has nondet. time complexity } T(n)\}$
- DSPACE(S(n)) = {L| L is a language  $\land$  L has nondet. space complexity S(n)}

#### 6.2 In terms of decision problems:

- DTIME $(T(n)) = \{D \mid D \text{ is a decision problem } \land L(D) \text{ has time complexity } T(n)\}$
- DSPACE(S(n)) = {D| D is a decision problem  $\land$  L(D) has space complexity S(n)}
- NTIME $(T(n)) = \{D \mid D \text{ is a decision problem } \land L(D) \text{ has non-det. time complexity } T(n)\}$
- DSPACE $(S(n)) = \{D | D \text{ is a decision problem } \land L(D) \text{ has nondet. space complexity } S(n)\}$

## 6.3 Relations between different complexity classes:

- DTIME $(T(n)) \subseteq DSPACE(T(n))$  i.e. What can be solved in time O(T(n)), can also be solved on space O(T(n))
- $L \in DSPACE(S(n)) \land S(n) \ge log_2 n \Rightarrow \exists c : L \in DTIME(c^{S(n)})$  i.e. What can be solved nondeterminstically in space O(S(n)), can be solved deterministically in (at most) time  $O(c^{S(n)})$
- $L \in NTIME(T(n)) \Rightarrow \exists c : L \in DTIME(c^{T(n)})$  i.e What can be solved nondeterministically in time O(T(n)), can be solved deterministically in (at most) time  $O(c^{T(n)})$ 
  - Consequentely, the substitution of nondeterministic algorithm with a deterministic one causes at most *exponential* increase in the **time** required to (deterministically) solve a problem.
- $NSPACE(S(n)) \subseteq DSPACE(S^2(n))$ , if  $S(n) \ge log_2n \land S(n)$  is "well behaved" i.e What can be solved nondeterministically on space O(S(n)), can also be solved deterministically on space  $O(S^2(n))$  Consequentely, the substitution of nondeterministic algorithm with a deterministic one causes at most quadratic increase in the **space** required to (deterministically) solve a problem.

## 6.4 Define P, NP, PSPACE, NPSPACE:

- $P = \bigcup_{i \ge 1} \text{DTIME}(n^i)$  is the class of all decision problems **deterministically** solvable in *polynomial time*.
- $NP = \bigcup_{i \geq 1} \text{ NTIME}(n^i)$  is the class of all decision problems **nondeterministically** solvable in *polynomial time*.
- $PSPACE = \bigcup_{i \geq 1} DSPACE(n^i)$  is the class of all decision problems **deterministically** solvable on *polynomial space*.
- $NPSPACE = \bigcup_{i \geq 1} NSPACE(n^i)$  is the class of all decision problems **nondeterministically** solvable on *polynomial space*.

#### 6.5 Relations between P, NP, PSPACE, NPSPACE:

$$P \subseteq NP \subseteq PSPACE = NPSPACE$$

Proof:

- $P \subseteq NP \rightarrow$  Every deterministic TM of polynomial time complexity can be viewed as a (trivial) nondeterministic TM of the same complexity.
- NP  $\subseteq$  PSPACE  $\rightarrow$  If  $L \in NP$ , then  $\exists k$  such that  $L \in$  $NTIME(n^k)$ . So  $L \in NSPACE(n^k)$ , and hence  $L \in DSPACE(n^{2k})$ . Therefore  $L \in PSPACE$ .

  • (PSPACE = NPSPACE)  $\rightarrow$  Trivially, PSPACE  $\subseteq NPSPACE$ .

  NP-hard:  $D \leq^p D^*$ , for every  $D \in NP$ .

  NP-complete:  $D^* \in NP \land D \leq^p D^*$ , for every  $D \in NP$ .

  Hence,  $D^*$  is NP-complete if  $D^*$  is in NP and  $D^*$  is NP-hard.

The opposite direction:  $NPSPACE = (def) = \cup NSPACE(n^i) \subseteq (by$ Savitch)  $\subseteq \cup$  DSPACE $(n^j) \subseteq$  PSPACE

6.6 NP-complete & NP-hard problems
